What is claimed is:

5

10

15

20

25

1. A rotor of a line start permanent magnet motor comprising:

a core provided with an axial hole for inserting an shaft and a plurality of penetrated magnet coupling holes formed at a periphery of the axial hole;

permanent magnets respectively coupled to the magnet coupling holes of the core;

a third end ring provided with magnet paths for respectively passing the permanent magnets and coupled to one side surface of the core;

a fourth end ring having the same appearance as the third end ring and coupled to another side surface of the core to be connected with the third end ring;

a magnet supporting plate positioned between one side surface of the core and the fourth end ring for preventing the permanent magnets from being separated; and

a fixing member inserted into the magnet paths of the third end ring for preventing the permanent magnets from being separated.

- 2. The rotor of claim 1, wherein the core is a stacked body that a plurality of circular thin plates having a certain thickness are stacked.
- 3. The rotor of claim 1, wherein inner diameters of the third end ring and the fourth end ring are formed to be smaller than a diameter of an inner tangential circle connecting inner tangent lines of the permanent magnets.
 - 4. The rotor of claim 1, wherein outer diameters of the third end ring

and the fourth end ring are formed to be larger than a diameter of an outer tangential circle connecting inner tangent lines of the permanent magnets.

- 5. The rotor of claim 1, wherein the magnet paths of the third end ring are formed as an inclined shape that a hole positioned at the core side is small and a hole positioned at the opposite side is large, and the fixing member inserted into the magnet paths is formed as a wedge shape which is the same as a shape of the magnet paths.
- 10 6. The rotor of claim 1, wherein a depth of the magnet paths of the third end ring and a length of the fixing member are equal.
 - 7. The rotor of claim 1, wherein the fixing member is formed of the same material as the third and fourth end rings.

15

- 8. The rotor of claim 1, wherein the permanent magnets are pressed-inserted into the magnet coupling holes of the core and thereby coupled.
- 9. The rotor of claim 1, wherein a slit having a constant width
 and length for preventing a magnet flux leakage of the permanent magnets is
 formed at the cylindrical plate in accordance with the permanent magnets.
 - 10. A manufacturing method of a rotor of a line start permanent magnet motor comprising the steps of:
- stacking a plurality of thin plates having a certain shape and thus

manufacturing a core;

5

10

positioning a magnet supporting plate to one side surface of the core;

forming third and fourth end rings having the same appearance by a die casting at both side surfaces of the core where the magnet supporting plate is positioned;

inserting a plurality of permanent magnets to the core through the third end ring and thereby fixing; and

respectively fixed-coupling a fixing member to the third end ring in order to prevent the permanent magnets from being separated.
